Perimeter Protection Systems – more important than ever

Security starts outside the building – CFPA Europe publishes first European training schedule for Perimeter Protection Systems

September 2013

Numerous public institutions, commercial areas and industrial buildings as well as their related open areas which are used for storage of material of all kinds are profitable targets for criminals and at the same time the security systems are often not a big challenge.

Security strategies for commercial and industrial buildings and areas usually focus on the protection of the building itself and its content. The use of mechanical intrusion protection systems, often in combination with intruder alarm systems is known and accepted by many building owners and insurers.

But today, due to the interdependence of processes even small interruptions may be followed by huge financial losses (e.g. due to just-in-time-concepts). In case of theft of special products from an outside storage area a whole supply chain can fail. Therefore comprehensive protection strategies are required to ensure an undisturbed and safe course of operation.

For many types of operation and sensitive infrastructures, traditional shell and internal protection is not sufficient. Exterior systems are necessary: perimeter detection and protection systems.

In the new European training course the users are trained in the detailed aspects of perimeter protection and detection which are described in common rules and recommendations. The knowledge which is substantial for the application is communicated. The participants learn about the components of perimeter protection and detection systems and are enabled to evaluate these on their effectiveness and usefulness – also considering financial aspects. Knowledge on calls for tenders and planning examples complete the know-how skills.

Further information on the seminar and the training organisations offering this course are available under cfpa-e.eu.
